THE EFFECTS OF CORPORATE SOCIAL RESPONSIBILITY PERCEPTIONS 
ON THE VALUATION OF COMMON STOCK

Abstract

We examine effects of intangible assets on financial viability and social perceptions on the market valuation of firms. The concepts of corporate financial performance (CFP) and corporate social performance (CSP) are introduced to account for variation and differences in financial viability, which in turn has an important impact on market to-book of assets. The results, using a sample of the top 100 corporate citizens as complied by KLD Research and Analytics, indicate that the relationship of intangible assets to total assets influences firms’ viability. The results also show that social perceptions have a significant impact on firms’ market valuations.
Introduction

Most attention to the ethical\textsuperscript{1} dimension of management has been devoted to a philosophical perspective, focusing on the question of how leaders ought to behave (Brown et al. 2005, p. 17). Further, engagement between managers and stakeholders has become an important theme in corporate environmental management literature and practice (De Bruijn and Tukker 2002). The literature on stakeholders’ engagement by firms gives little consideration to the influence of stakeholders affect on the market valuation of a firm from a modeling perspective. This paper seeks to address these omissions, examining how and why stakeholders influence market valuation by drawing on a sample of select firms viewed as being corporate responsible citizens.

One way to examine ethical and social responsible organizations over a number of years is to examine its corporate financial performance (CFP) in relationship with corporate social performance (CSP) information. CSP is defined as a voluntary business action that produces social (third party) effects (Schuler and Cording 2006). The interest in this reflection of moral and value system as drivers in organizations along with CFP is viewed along with today’s rapid growth of sustainable investment (Winnett and Lewis 2000). For example, at least over one trillion in assets are under management in the United States in social and environmentally responsible portfolios (Ethical Investor Newsletter 2001).

Gardberg and Fombrun (2006) indicated that CSP activities are due to an altruistic or instrumental standpoint for the possible benefit to companies. Schuler and Cording (2006) advocated that in order for markets to exhibit some degree of control over CSP, information must be available to stakeholders about the organization’s social practices. Schuler and Cording (2006, p. 556) further stated, “to fully explain the link between CSP and CFP, the decision-making processes of stakeholders must also be illuminated”.

\textsuperscript{1} Morality or ethics is defined as a set of standards by which humans regulate their behavior in order to achieve the purpose of life. One component of ethical decision making is the actual moral judgment, where the final determination of right and wrong is made. Everyone makes moral judgments about the goodness and badness of people, the rightness and wrongness of behaviors, and the rights and duties of members of groups. The significant question to be thought of is “Which kinds of behavior are moral or immoral?".
This research article seeks to use a decision making model in order to depict CSP information as drivers of common stock valuation. Some have argued that although many act unethically because they intend to, others simply do not recognize the moral aspects of the situations in which they are involved and thus do not initiate the moral decision making process (Reynolds 2006, p. 233). Such explanations have been applied to some of the great ethical scandals of our time, including Enron, Worldcom, Tyco, Parmalat, and Ahold (Currall and Epstein 2003, Flowerday and von Solms 2005, Lev 2002) and “imply that by improving managerial moral awareness, future ethical catastrophe can be avoided” (Reynolds 2006, p. 233).

Ethical and social responsible investments (such as “green”, environmental and sustainable mutual funds) are not a new phenomenon; social changes in society due to considerations of applied ethics can be traced over time for thousands of years. The assumption is that ethical, social and environmental responsible investments will have a more probable influence on individuals’ and organizations’ ethical behavior than what governments’ regulations will have. One explanation for this is a bi-assumption that “money will talk more effectively”. These beliefs tend to be held by those who argue that ethical and social responsible investments are effective in some sense that goes beyond individual conscience salving (Winnett and Lewis 2000).

Previous studies have suggested that CSP appears to be more highly correlated with accounting-based measures of CFP than with market-based indicators, and CSP reputation indices are more highly correlated with CFP than are other indicators of CSP (Orlitzky et al. 2003), or that CSP and CFP are inconclusive (McWilliams and Siegal 2001). Our research extends previous work by examining how CSP and CSF are linked in a two stage decision making model. That is, by providing a process approach, we are able to look inside the “black box” in order to determine if CSP and CSF affects both the intermediary stage and final stage of market valuation of stock. First, this approach advances the literature in that where previous studies indicated conflicting results; this may have been due to different stages of
influence for CSP and CSF information. Second, matching a conceptual model with a covariance structural model could provide new insights regarding the importance of the interactions of CSP and CSF.

Our study of the top 100 corporate citizens complied by KLD Research and Analytics (http://www.business-ethics.com) provides important evidence that the relationship between CSP and market-to-book of assets may not be mediated by financial viability that reflects profitability, liquidity and leverage measures, but CSP has a direct impact on market value. We hope that this manuscript motivates research that explores the interactions between CSP and CFP. The next section explains the decision making model used to capture the impact of financial information and corporate social responsibility perceptions on judgments and decisions.

DECISION MAKING MODEL

Much has been debated in terms of whether firms should orient themselves toward a shareholder or stakeholder perspective (Sundaram and Inkpen 2004). The aim of our paper strives to identify if managers and stakeholders identify a common core value such as CSP as it is related to the market valuation of a firm’s stock (Freeman and McVea 2001). Although Mitchell et al. (1997) reviewed the literature and developed a list of 27 different definitions of stakeholders, we hope to draw some coherence in the literature by identifying the ethical and social responsibility dimension as a significant component to the stakeholder literature (De Bruijn and Tukker 2002).

We present a theoretical model that attempts to clarify the multiple ways in which intangible assets and social perceptions can increase or decrease firms’ value. This Throughput Model (Rodgers 1997) captures different pathways and stages that can influence a decision at the individual or organizational level. The model proposed here also provides a broad conceptual framework for examining interrelated processes that impact on decisions effecting organizations (Figure 1). It incorporates the constructs of perception, available information, judgmental processing (analysis of information/perception), and
decision choice as it applies to individuals/organizations (Rodgers 1997). We believe that our analysis can support or disconfirm two broad of “stakeholder contract costs theory” and “good management theory.”

The stakeholder contract costs theory assumes that the benefits of CSP outweigh the costs, whereby stakeholders exercise some social control over a firm (Waddock and Graves 1997). Hence, companies provide resources on CSP activities leading to CSP contributing to CFP. Good management theory implies that managerial skills and strategies are needed for good financial performance (Waddock and Graves 1997). Hence CFP results from CSP. Our model can be tested to determine whether the data support or not support the stakeholder contract costs theory or good management theory.

The central insight of the decision-making model is that CSP information inputs are embedded in a social contract. This insight we depict as “perception” in our model. Judgment (financial viability), the second stage, involves a more detailed analysis of CFP and CSP. Decision choice is the final stage of processing. This stage represents a culmination of information, perception and judgment (see Figure 1).

*Information* includes the set of financial and non-financial information for reporting purposes by firms. In this model, profitability, liquidity, leverage and intangible information (I) as well as social perception (P), measured by customer, employee and community relations, affects financial viability judgment (J). Intangible information is included in our model since firms report on assets that have been purchased (e.g., brand names, copyrights, patents etc.). However, we claim that this information differs from CSP information since the current accounting rules do not require firms to report CSP (Rodgers 2003).

The *judgment* stage contains the process firms implement to analyze incoming information (financial and non-financial), as well as the influence from the perception stage (i.e., social perceptions). The direct path from social perception to judgment implies that CSP contributes to CFP, thereby providing credence to the stakeholder contract costs theory.
Finally, the decision choice stage reflects the market valuation of a firm. Social perception and judgment can affect decision choice (D) of common stock valuation. Social perceptions’ direct influence on decision choice (market-to-book of assets) is an indication that CFP results from CSP. That is, CSP can influence market valuation of common stock.

**HYPOTHESES DEVELOPMENT**

**Financial viability and intangibles**

Financial profitability and other financial measures provide useful CFP information on a firm’s short-term performance. In evaluating a firm’s long-term performance, however, other non-financial data can provide incremental information. In this paper, we propose a model in which, in addition to financial performance, other information can be valuable in evaluating and predicting a firm’s long-term performance (see Figure 2). In this model, both the firm’s financial viability and investors’ CSP perception of the firm’s commitment to meet its social responsibility play a significant role in determining the firm’s market value. Financial viability of a firm is reflected by traditional financial measures such as profitability, liquidity and leverage. However, as argued in prior studies (Amir and Lev 1996, Lev and Sarowin 1999, Demers and Lev 2001, Trueman et al. 2000), financial reports of firms, high-tech firms in particular, reflect a firm’s value with distortion. Investors realize such a distortion and incorporate other non-financial information when they evaluate the value of a firm. In other words, these prior studies suggest that non-financial information is an important determinant of a firm’s market value.

One non-financial information that has widely been identified as “value-relevant” is the intensity of research and development. Current accounting standards (GAAP) require firms to write their investment in research and development off as expenses. Only a limited number of intellectual properties can be recognized as assets on a firm’s balance sheet (e.g., software). Consequently, the product of these
research activities cannot be recognized as assets on the balance sheet even when they generate revenues for the firm. In other words, assets of firms with intense research and development activities are understated. Chan, Martin and Kensinger (1990), Shortridge (2004), Joos (2002), Jennings, Robinson, Thompson, and Duvall (1996) and Liu (2006) document that market does incorporate the value of research and development and other intangibles, such as goodwill, in their valuation models. This relation is depicted by our model predicting that intangible assets have an impact on firm’s financial viability:

*Hypothesis 1. A firm’s financial viability depends on the portion of total assets that is intangible.*

However, are these intangible assets the only value-relevant information missing from the financial statements? Are there any other assets contributing to a firm’s market valuation but are not recognized by accounting standards as well? In this paper, we examine the effect of these other “intangible assets”—employee, customer, and community relations—on a firm’s value. To this end, our model conceptualizes that, in addition to the financial viability of a firm, investors incorporate their perception of the firm’s commitment to meet corporate responsibility in their valuation decisions.

**Employee, Customer and Community Relations**

With the significant growth in high-tech firms, the competition for talents in the labor market has been more intense than ever (Collins and Smith 2006, Ballou et al. 2003). Firms use various long-term compensation schemes, such as stock options and restricted stock grants with several years of vesting period, to retain their employees. Still other firms tried more innovative ways to attract employees. The enormous spending on employee stock options, restricted stocks, and other employee compensation indicates the importance of human resource. Also, from a list of top 100 employers to work for constructed by Fortune magazine every year, we can learn the extra mile firms are willing to go to ensure their employees are satisfied. Wegmans Food Markets, who topped the 2005 list, states its motto as “Employees first, customers second”. With such a corporate belief, this retailer was able to keep its annual turnover rate (6%) three times lower than other grocery stores with similar size (19%). Microsoft also made the list because of its generosity towards employee compensation, medical benefits, and the
matching for employee charitable donations. Proctor and Gamble was one of the most innovative in that it paired up senior manager (mostly male) with junior female employees in order for the senior manager to understand issues these junior employees face. All these examples demonstrate the importance of employee satisfaction.

Human resource is an important determinant of a firm’s productivity, profitability, and its long-term survival. Unfortunately, this important “asset” of a firm is not recorded anywhere on a firm’s balance sheet. However, with its significant impact on a firm’s long-term well-being, we anticipate investors account for this employee satisfaction factor in their investment decision and the market incorporates this human resource factor into its pricing of a firm.

In addition to happy employees, it is equally important that a firm’s customers are satisfied with its products and/or services (Luo and Bhattacharya 2006, Maiga and Jacobs 2005). Companies spent millions and millions of dollars to improve their products/services, cater for the needs of customers, and advertise to promote their products to customers. Moreover, they set up customer relations department to cultivate and maintain a long-term relationship with customers. A well-maintained customer relation helps to retain old customers for repetitive businesses, build up customer loyalty, and attract new businesses by the word of mouth. The costs of keeping existing customers are likely to be lower than those of acquiring new customers (Voss and Gruber 2005). Retention of existing customers is particularly important for a company operating in a mature industry (Reichheld 2003). A satisfied customer will come back and purchase goods or services in the future, generating revenues in the long run. These loyal customers will also recommend the product or service to their friends. This saves the firm’s expenditure on marketing. This word-of-mouth type of promotion can be particularly beneficial for firms in mature industries because the large marketing costs of acquiring new customers through advertising and other promotions can make the firm hard to grow profitably (Reichheld 2003).

While these customer-relation efforts have both short- and long-term benefits, only the short-term benefits are recognized as sales on financial statements. On the other hand, all such costs incurred in
improving and promoting the products in the current period are recorded as expenses on the income statement. Without accounting for the customer relation or brand name on the financial reports, these financial statements again understate the “assets” of a firm. If the market realizes the value of brand name and/or customer relation to a firm, investors will incorporate this information in their pricing.

Besides improving relation with current employees and customers, it also helps a company to cultivate its relation with potential employees and customers. One way to achieve this is to have a good community relation. Maintaining a good community relation promotes the image of a company. A good company image contributes to a good brand name. For example, Ford Motor was selected Latina Style magazine’s 2004 Fifty Best Companies based on, among other criteria, its mentoring program and its relationship with the Hispanic community (http://media.ford.com/newsroom/feature_display.cfm?release=20131). This publicity provides Ford an alternative way to reach customers, employees, and other constituents, in addition to the traditional advertising campaign. By actively participating in community programs, either through charitable donation, sponsorship, and/or setting up policies to encourage employees to volunteer, firms can promote their brand name. We expect this long-term relationship with the community improves investors’ perception of the company and likely leads to an increase in its market value. These arguments lead us to our second hypothesis:

_Hypothesis 2. In addition to the financial viability of a firm, investors incorporate their perception of the firm’s efforts to improve their employee, customer, and community relations in their valuation of the firm._

**METHODS**

In order to test these hypotheses, we use the employee and customer satisfaction, and community relation indices provided on Business-ethics.com (http://www.business-ethics.com). Each year, the website generates a list of top 100 corporate citizens based on data provided by KLD Research and
Analytics. Business-ethics.com started generating the list in year 2000. The list is constructed based on the points a firm scores in the welfare measures of four stakeholder groups: the customer, employee, community, and stockholders. Over the years, the criteria have gradually expanded to include the welfare of seven stakeholders. However, in order to provide a consistent comparison over years, we include only the initial four stakeholder groups in our analyses. Our sample is composed of 233 observations between 2000 and 2003.

For each stakeholder group, KLD Research and Analytics identified the strengths and concerns of a firm in that area. The number of concerns was then subtracted from the number of strengths to arrive at a net score. This net score was then standardized by the mean net score of each stakeholder category. That is, KLD used the number of standard deviations a firm’s scores was from the mean of each stakeholder category as a measure of the firm’s points received in that category. An overall score for a firm is then computed using the unweighted average of points received in all stakeholder categories. This constitutes the overall social responsibility standing of a firm.

For the customer category, KLD examines whether the firm has a quality management program and its quality, any quality awards the firm has won, customer satisfaction measure, any customer lawsuit pending, etc. In the employee relation category, KLD considers, among other criteria, employees’ wages relative to the industry, benefits, employee empowerment, family-friendly policies, and other policies the firm has in place to accommodate employees’ needs. The factors considered in the community relation category includes whether the company has any foundation, community service projects, employee volunteer programs, etc.

We took the scores a firm receives in the customer, employee, and community categories from the website and rank them relative to other firms that made the top 100 list in the year. We use the relative ranking in each category as a proxy for the quality of its customer, employee, and community relations. In addition, we use the overall social responsibility score a firm receives as a proxy for the general perception investors have regarding the firm or the image a firm projects to the general public.
Besides the non-financial measures, we include a firm’s financial viability in our analyses. This provides us with a benchmark on how much the non-financial measures contribute to the overall market value of a firm relative to the financial viability. We retrieve the financial data required for the computation of a firm’s financial viability from Compustat. We use the Zmijewski score (Zmijewski 1984) as a proxy for the financial viability. This financial viability score measures a firm’s probability of going bankrupt. The higher the score, the higher the probability of a firm going bankrupt is. The score is constructed based on a firm’s profitability, liquidity, and leverage ratios as follows:

\[ ZFC = -4.336 - 4.513 (ROA) + 5.679 (FINL) + 0.004 (LIQ) \]

where \( ROA \) is the return on assets, \( FINL \) is the financial leverage, and \( LIQ \) is the liquidity measure.

In addition to these traditional measures of a firm’s financial healthiness, we incorporate a firm’s intangible asset in our analysis of a firm’s financial viability. The growing importance of intellectual properties in firms indicates that these intangible assets play a critical role in a firm’s success. As documented in prior studies, investors do account for the intangibles in their valuation of a firm. However, most prior studies document the effect of research and development, an intangible unrecorded on financial statements. In this study, we investigate the effect, if any, of intangibles that are already recorded as assets on a firm’s financial viability. Given two firms with the same profitability, leverage, and liquidity levels, will they have different financial viability if intangibles constitute a larger portion of one firm’s assets than that of another firm?

We use the goodwill to total assets and intangibles to total assets as measures of the portion of a firm’s assets that is intangible. We then examine what effect these intangibles, if any, has on the financial viability of a firm and the portion of financial viability attributed to the intangibles versus that attributed to the profitability, liquidity and leverage ratios. We use the return on assets (ratio of net income to total assets) and the net income to sales ratio to measure a firm’s profitability. A firm’s liquidity is again

---

2 Numerous accounting studies have used Zmijewski score for the recognition of financial distressed firms (e.g., Ruiz-Barbadillo et al. 2004, Johnstone and Bedard 2004, Carcello and Nagy 2004).
measured by two indicators: the quick ratio (the ratio of sum of cash, marketable securities, and receivables to current liabilities) and the ratio of current assets to current liabilities. Leverage is measured by the ratio of total debt to total assets and the ratio of long-term debt to total assets. Finally, the market’s valuation of a firm is measured by the market-to-book of assets.

RESULTS

We used Partial Least Squares (PLS) to analyze our research model depicted in Figure 1. PLS is a latent structural equation modeling technique that allows the researcher to test the relationship within the measures (the measurement model) and the hypothesized relationship among the measures (the structural model) simultaneously (Lohmoller 1989, Wold 1982). It is particularly useful for studying structural models involving multiple latent constructs with multiple indicators.

There are three main advantages of PLS. First, unlike other structural equation models (LISREL, AMOS, EQS, etc.), the assumptions underlying PLS are less stringent (Fornell and Bookstein 1982, Lohmoller 1989, Chin et al. 2003). PLS imposes minimal restrictions on measurement scales, sample size, and residual distributions. That is, since regression coefficients are estimated iteratively in PLS, sample size is normally not a problem. Second, PLS has superior ability to handle causal-predictive analysis in situations of high complexity but low theoretical underpinnings. PLS uses a principal-component model in which no random error variance or measure-specific variance (i.e., unique variance) is assumed. Parameters are estimated in a manner that maximizes the amount of explained variance in a set of observed measures. Goodness of fit is evaluated on the basis of the percentage of variance explained in the specific regression. Because the PLS approach estimates the latent variables as exact linear combinations of the observed measures, it offers the advantage of exact definition of component scores. Third, PLS can handle and test complex constructs with both reflective and formative factors (Chin 1998). In Figure 1, “profitability”, “liquidity”, “leverage”, “intangibles”, and “social responsibility information” are latent constructs measured by formative indicators of our research model; whereas “viability”, “social perception”, and “market value” are measured by reflective factors.
In PLS, loadings of measures of each construct can be interpreted as loadings in a principal components factor analysis. Paths between latent constructs can be interpreted as standardized beta weights in a regression analysis. Because PLS does not make distributional assumptions, traditional parametric procedures of significance testing are not appropriate. Thus, we use bootstrapping resampling procedures to estimate factor loadings and path coefficients in the model (Chin 1998). Table 1 summarizes descriptive statistics for indicators.

**Measurement Validation**

Our model was estimated using the computer program PLS-Graph version 3.00. The measurement model evaluates the relationship between indicators and latent constructs by assessing the reliability and validity of the scales measures. Each measure’s reliability is assessed by examining the loading of the indicators on the corresponding construct. All measures have a loading level above 0.70, except for one measure of “leverage” that has a loading of 0.65 (see Table 2). In addition, measurement residuals are small. All loadings have the expected signs (i.e., non-negative) and are statically significant at the 0.001 level (one-tailed). Further, all constructs present a composite reliability (see, Fornell and Larcker 1981) above 0.70, the benchmark level suggested by Nunnally (1978).

Also, convergent and discriminant validity can be evaluated within the PLS model. According to Chin (1998), convergent and discriminant validity is inferred when the PLS indicators (1) load much higher on their hypothesized factor than on other factors (i.e. own-loadings are higher than cross-loadings), and (2) when the square root of each construct’s Average Variance Extracted (AVE) is larger than its correlations with other constructs (the average variance shared between the construct and its indicators is larger than the variance shared between the construct and other constructs).

To test the first condition, the CFA procedure in PLS was performed. That is, an examination of measure loadings on constructs correlations. The correlation matrix in Table 3 shows that no indicator
loads more highly on another construct than it does on the latent construct it is intended to measure. Convergent validity of a construct is measured by the ratio of the variance of its indicators captured by the construct to the total amount of variance (“average variance extracted” $O_{UC}$). The total amount of variance includes the variance due to measurement error. As a rule of thumb, a ratio of less than 0.50 implies the convergent validity assumption is violated because more variance is explained by the error than the construct. In our model, average variance extracted ($O_{UC}$) ranges between 0.65 and 1.00, indicating satisfactory convergent validity for the constructs.

Satisfactory discriminant validity among constructs is obtained when the squared correlation between any two constructs is statistically less than the $O_{UC}$. This implies that the variance shared between any two constructs is less than the variance shared between a construct and its indicators (see Fornell and Larcker 1981). The low and moderate average squared correlations among constructs in Table 2 show that our model also satisfies the condition for discriminant validity. Another meaningful indicator of the fit of the model with respect to its measurement is the overall communality coefficient (in our model 0.81). This exceeds Falk’s (1987) recommendation that this coefficient should be greater than 0.30. Thus, it can be concluded that the constructs are measured with sufficient precision, that is, the model is both reliable and valid.

The Structural Model

The PLS path coefficients are shown in Figure 2. Consistent with our expectation, companies with high financial viability (i.e. low Zmijewski score) are more profitable ($p < .001; R^2 = .339$), more liquid ($p < .001; R^2 = .200$), and less leveraged ($p < .001; R^2 = .839$) firms. Further, the proportion of intangible assets has a significantly positive impact on the financial viability ($p < .001; R^2 = .097$) latent construct, supporting Hypothesis 1. This result suggests that the larger the portion of total assets that is made up of intangibles, the more susceptible the firm is to bankruptcy, as measured by Zmijewski score. This result seems to contradict results in prior studies that document a positive effect of unrecorded
intangibles (e.g. research and development) on a firm’s profitability. One potential explanation is that firms with large recorded intangible assets are also those with large unrecorded intangible assets. As Zmijewski score assesses a firm’s bankruptcy probability based on a firm’s recorded assets and liability, it is likely that these firms with significant unrecorded intangible assets receive high Zmijewski score (i.e. high bankruptcy probability). Consistent with the results in previous research, the financial viability latent variable has a significantly negative effect on the market value of companies ($p < .001$). In other words, companies with lower financial distress are those with higher market value.

A firm’s efforts in meeting the needs of its various stakeholders—employees, customers, and the community—has a significant influence on the market’s perception of the firm’s commitment to meet its social responsibility ($p < .001; R^2 = .909$), which in turn, has a significantly positive effect on the firm’s market value ($p < .001; R^2 = .306$). This supports our Hypothesis 2. On the other hand, the social perception does not have any significant effect on a firm’s financial viability. Thus, the social perception of a firm’s commitment to meet corporate responsibility contributes directly to the firm’s market value, rather than affecting it indirectly via the financial status of the firm.

**CONCLUSION, LIMITATIONS AND FUTURE RESEARCH**

The decision model used in this study implies that intangible assets (CSP) influencing financial viability (CFP) depict stakeholder contract costs theory. Further, our study indicates that social perceptions (CSP) can have a direct impact on a firm’s market valuation implying those managerial skills and strategies are indirectly influencing financial performance (i.e., “good management theory”). Therefore, the decision model helps identify the different aspects of the model that both theories are important in explaining the relationship between CFP and CSP.

In addition, the results of our study support the notion that firms’ viability is dependent on its relationship of intangible assets to total assets. Whereas, previous studies have emphasized that unrecorded intangibles have a positive effect on firms’ profitability, we believe that additional research
should be conducted in order to test whether firms with large recorded intangible assets are also those with large unrecorded intangible assets as related to bankruptcy measures.

Another major finding in this study underscored the view that social perceptions are influential in determining market valuation of firms. That is, future research may uncover other relationships with other important market factors along with social perceptions in a model setting.

A limitation of this study involves the tenuous relationship between CSP and CFP due to their measurements, as well as the sample used in this study (Griffin and Mahon 1997). In sum, to endure and build long-term value for shareholders, firms must also do well by society. Issues of firms’ sustainability lie in synergies with customers, employees, and the community as well as how the firm integrates with the community in a global context. Social responsibility and community relations could be important to firms’ growth and profitability; however, much work is needed in terms of how to measure and report intangible assets. Overall, our results suggest that taking into account a firm's broader societal strategies leads to a material shift in value when compared to standard financial analysis. Therefore, if social perceptions are unincorporated in financial reporting, then there is value at stake for firms that understand these issues and can adapt them to their own businesses.
