An Analytical Regions Proposal for the Study of Labour Markets: An Evaluation for the Spanish Territory

Ana Viñuela Jiménez (*)

Fernando Rubiera Morollón (*)

Abstract :

Internal homogeneity and also heterogeneity between the regions are both desirable properties for a better understanding of the local labor markets and for increasing the efficiency of any industrial policy applied at local level. However, studies of the labor markets that include a spatial dimension are commonly limited to administrative rather than appropriately-defined functional regions. Using micro data from the latest Census available, the Spanish territory can be divided into functional regions that emphasize the importance of location and agglomeration economies (size). The objective of this paper is to prove that, when studying labor economic issues, such classification based on economic criteria results on more convenient regions than the administrative ones commonly used (NUTS regions). Based on this simple idea, the results from this study suggest that, subject to the availability of data, this alternative spatial division should be considered when carrying out labor economics studies at a sub-national level.

Keywords: regions, urban and regional economy; cluster validation, local employment and Spain.

JEL Classification: R23 and R12.

1. Introduction.

Economic data is usually spatially disaggregated according to the administrative or normative division of the territory. Unless having access to the original micro databases, it implies that any spatial analysis will be limited to the use of those administrative regions. However, such regions do not necessarily make economic sense as they are or were constructed in terms of some sort of political, administrative or historical criteria.

Using normative regions is the common practise, but in many cases statistical inference based on this division may be strongly affected by aggregation problems such as the ecological fallacy (Robinson, 1959)¹ or the modifiable areal unit problem (Openshaw 1984)². In other words, the area or region created is not necessarily homogeneous, which is also referred to as aggregation bias in the literature³.

Overall, instead of considering alternative spatial divisions, regional scientists have been devoted to formulating statistical models or estimation procedures to reduce the aggregation bias⁴. If having access to micro databases, researchers can carry out their own regionalization procedure in order to create analytical or functional areas that are conveniently related to the phenomena under examination optimizing a particular aggregation criterion⁵.

In case of dealing with labour market issues, internal homogeneity and also heterogeneity between the regions created would be both desirable properties for a better understanding of the local labor markets (Fischer, 1980) as well as for increasing the efficiency of any industrial policy applied at local level (Coombes et al. 1986). Nonetheless, the existence of agglomeration economies should not either be forgotten. As well as they determine location decisions and specialization patterns for companies, they should also explain the same for workers.

¹ EF was first introduced by Robinson (1950) and has been studied by many other authors since then. See, for example, Richardson *et al.* (1987), Piantadosi *et al.* (1988), Greenland and Morganstern (1989) and Richardson (1992).

² See also Openshaw and Taylor (1981) and Arbia (1989).

³ See Fotheringham and Wong (1991), Amrhein and Flowerdew (1992), Paelink and Klaassen (1979) or Paelink (2000).

⁴ Gotway and Young (2002) provide a detailed overview of several statistical solutions that have been proposed to deal with this problem.

⁵ See Duque *et al.* (2007) for a review of supervised regionalization methods.

The purpose of this study is not carry out a regionalization exercise to generate internally homogeneous or well differentiated labour markets according to one or several variables, but to prove that a functional classification based on the existence of agglomeration economies and the importance of location results on more convenient regions for the study of labour markets issues than the administrative ones commonly used (NUTS regions). Evenmore, this economic criterion not only creates compact and well differentiated labour markets, but also allows the segmentation of the whole territory⁶.

The rest of the paper is organized as follows: in the next section we discuss the meaning of *regions* and describe the aggregation criteria used for creating regions with economic sense based on agglomeration economies and the importance of location. Applied to the Spanish case using data for the latest Census available, Section 3 deals with the evaluation of these functional regions *versus* the administrative ones commonly used for studying the spatial dimension of the labour markets. Internal homogeneity within the regions and heterogeneity between them when dealing with the distribution patterns of employment are evaluated by gender, industry and level of qualification. In the light of the results of such evaluation, in the last section we summarize the main conclusions of this study.

2. Surpassing the administrative regions: an analytical proposal for the analysis of the labour markets in Spain.

What is region? From an economic point of view, a *region* is a unit in which capital and labour move freely and goods and services are totally open to trade with other regions without any frontiers or limitations⁷. The openness and the interaction with other regions are their main characteristics.

From this basic idea, a particular territory can be divided into parts or regions using different criteria. However, three elements must be taken into account (Behrens and Thisse, 2007). First, a *Region* is part of a set in which each comprising element has some specificities which make it different from the rest.

⁶ To date, in Spain no exercise to identify well defined functional regions to study labour market issues has been carried out. There are either studies focused on exclusively one administrative region (Comunidad Valenciana in Casado-Díaz, 2000) or studies at national level dealing only with the metropolitan areas (Boix and Veneri, 2009).

⁷ See Polèse (2010) for a discussion.

Secondly, a set of regions always involves a partition of some geographical space that contains a large number of places, with a place serving as the elementary spatial unit that we use. Thirdly, a well-known result in set theory is that there is one-to-one correspondence between the family of partitions in a set and the family of equivalence relations of the same set⁸. Based on these three basic criteria, many possible sets of regions may be defined, and as a result, depending on the point of view selected, many types of concepts of *region* can be constructed.

In labour economics, data constraints have led to a situation where any research dealing with the regional or spatial dimension of the labour markets is usually based on administrative regions such as NUTS regions in the European case⁹. Some attempts have been made to use another spatial aggregation of the data reflecting functional relationships between workers and jobs. In those cases, the basic principle for setting the boundaries of the local labour markets (LLMs) is demand-side and supply-side self-containment, which in practical terms means maximizing (minimizing) commuting flows within (between) them¹⁰. The regionalization procedure commonly used consists on a multi-stage aggregation process based on an algorithm originally developed by Coombes et al (1986), and since then applied to many countries, including Great Britain (where the Department of Employment defines the so-called Travel-To-Work-Areas or TTWAs), Italy (Sforzi et al., 1997), for Spain (Casado-Diaz, 2000; due to the lack of data local labor markets for only one *comunidad autónoma* are computed), New Zealand (Papps and Newell, 2002), Denmark (Andersen, 2002) and Australia (Watts, 2003).

⁸ An equivalence relation in a set is a (i) reflexive, (ii) symmetric and (iii) transitive relation: these imply that (i) an object is always similar to itself; (ii) if one object is similar to another the latter is similar to the former and (iii) two objects similar to a third one are themselves similar.

⁹ Nomenclature des Unites Territoriales Statistiques (NUTS) is the geographical system established by the Eurostat for the production of regional statistics within the European Union. According to Eurostat, these “normative regions are the expression of a political will; their limits are fixed according to the task allocated to the territorial communities, to the sizes of population necessary to carry out these task efficiently and economically, or according to historical, cultural and other factors” (Eurostat, 2006).

¹⁰ In practice, that means setting a threshold of residents working in the area and workers living in the area (from 75% to 70% depending on population size) and also a minimum number of working population (commonly 3,500). See Ball (1980) and Coombes and Openshaw (1982) for more details about LLMs definition.

However, from a pure Regional and Urban Economics perspective (see Fujita *et al.* 1999), when defining a *region* a small number of attributes should be highlighted, namely: (i) location matters, because industries (and therefore economic activity and employment) are always drawn to places best suited for commerce and interaction with markets; and (ii) size matters, because dynamic industries, or the most advanced in each epoch, are naturally drawn to large cities and places within easy reach. A corollary could be deduced from (i) and (ii), namely (iii) proximity to size also matters¹¹. The existence of agglomeration economies (size) and the location are the key factors of this definition.

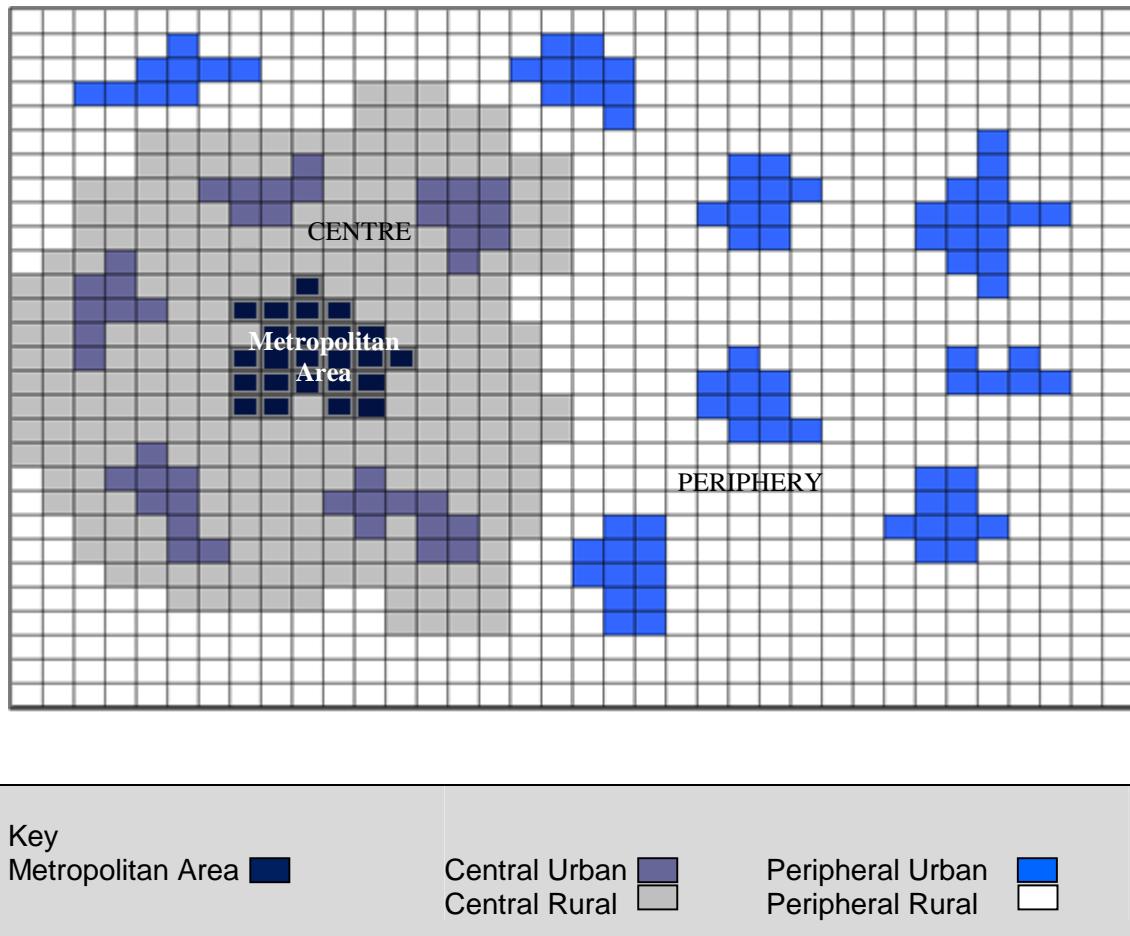

Taking these ideas into consideration, Coffey and Polèse (1988), Polèse and Champagne (1999) and Shearmur and Polèse (2004) suggest a functional classification which, though originally thought for explaining the location of economic activity and economic growth, could also be very useful for labour market analysis. As well as agglomeration economies and location determine location decisions and specialization patterns for companies, they should explain the same for workers (employment). In practical terms, with the functional classification the spatial statistical units (either census divisions, counties, municipalities, *länders*, etc) that constitute the national economic space are aggregated based on the population size and distance to the metropolis. Thus, these new analytical regions created are groupings of analogous statistical units, classified by size and by distance (to the nearest metropolitan area).

Figure 1 presents a schematic representation for an idealized national space economy. The reader will undoubtedly note the resemblance with the classic idealized economic landscapes of Christaller, Lösch, and Von Thünen, all of which posit one metropolis or marketplace at the centre. Thus, Figure 1 represents one big metropolis at the centre, but also four smaller “central” urban areas of different population sizes around it, as well as other “central” rural areas (these areas, either urban or rural, are close to the metropolis). Another four analogous size classes represent the “peripheral” urban areas, which are located at some distance from the metropolis and surrounded by their

¹¹ Another basic idea of regional economics is that (iv) cost matters, because without adequate size or a propitious location, places will grow if they have a clear labour cost advantage or, alternatively, an exceptional resource endowment (Polèse, 2010).

corresponding rural areas. It is implicitly assumed that urban areas are distributed in accordance with the rank-size rule¹².

Figure 0. Schematic Representation of the Classification of Spatial Units.

Source: Own elaboration based on Polèse et al. (2007).

¹² This was proposed by George Zipf (Zipf, 1949) and consists of identifying a statistical relationship between the size of cities and their position in the city ranking. The rule has been tested for several countries and time periods, with prominent empirical studies including Gabaix (1999) and Ades and Glaeser (1995).

Following this classification, in relation to size there are three main types of areas:

Metropolitan areas: metropolitan areas of more than five hundred thousand inhabitants. These metropolitan areas include the city and its surrounding area of influence. They are ad hoc specifications.

Urban areas: urban agglomeration areas with more than ten thousand inhabitants.

Rural areas: less than ten thousand inhabitants, including all areas that are not urban but which may contain towns.

A parallel distinction, based on proximity to major metropolitan areas, is applied to all non-metropolitan urban areas:

Central areas: all areas within approximately one hour's drive of a metropolitan area.

Peripheral areas: all areas situated more than one hour's drive from metropolitan areas.

The one hour's drive criterion takes into account several factors such as road conditions (e.g., highway or not), the spatial limits of metropolitan areas, and the distinctive characteristics of the area being classified. Thus, as illustrated on Figure 1, central areas do not necessarily form perfect rings around metropolitan areas. The one-hour threshold, also used in other applications, has been found to be very robust and a good indicator of the range within which spatial interaction with the metropolis remains fairly easy, especially for face-to-face relationships related to the consumption of high-order services.

Applied to the Spanish territory in Polèse *et al.* (2007) to explain the location of economic activity and in Viñuela *et al.* (2010) to explain employability patterns, in reality this classification based on economic criteria results on a picture quite similar to Figure 1, but with two big metropolitan areas (see Map 1).

Spain is divided into seventeen Autonomous Communities (NUTS II regions), some of which include several provinces (NUTS III) for a national total number of 50 provinces¹³. Each province is in turn divided into several municipalities,

¹³ Ceuta and Melilla are excluded from the study.

ranging from 34 (Las Palmas) to 371 (Burgos). Furthermore, the seventeen Autonomous Communities are also aggregated into seven administrative regions (NUTS I regions), which have no real internal meaning and are only used for comparative purposes with some other European member-states. In 2001 Spain had 8,106 municipalities. The Spanish Census gives population and employment figures (by age, gender, industry and level of qualification and occupation) for each municipality.

In the presence of agglomeration economies, economic activity and therefore employment tend to be unevenly spatially distributed, instead exhibiting positive spatial dependence. These disparities and spatial dependence can be observed at regional level either using the NUTS I, NUTS II or NUTS III regions.

For example, in the year 2001 the Spanish employment rates¹⁴ for the NUTS I regions ranged from 50.67% (South) to 62.72% (Madrid). At the NUTS II regional level, the figures ranged from 49.44% (Andalucía) to 63.65% (Cataluña), while for the NUTS III regions, the province with the lowest employment rate was Cádiz (43.45%) and the one with the highest was Girona, with 65.98% employment rate. To get a better idea of the magnitude of these disparities, Table 1 and 2 show the average and the standard deviation for NUTS I, NUTS II and NUTS III regional employment rates.

Table 0. NUTS I regional average employment rates.

NUTS I. Average Employment Rates

TOTAL	Average	57.77%	Standard Deviation		0.099

Source: Authors' calculations based on 2001 Spanish Census (INE, 2007).

¹⁴ Although EUROSTAT provides figures for employment rates for the NUTS I, NUTS II and NUTS III regions, for comparison purposes with the analytical regions under evaluation these figures have been calculated from the corresponding aggregation of the municipal data. Moreover, when using the 2001 Census from the Spanish National Institute of Statistics (INE), employment rates can only be estimated with the *potential* active population, i.e., all the population aged 16 to 64, either active or non active.

The wide disparities observed at NUTS I, NUTS II and NUTS III level reflect little or no consideration for the meaningfulness of these administrative or normative regions, which are the ones commonly used when studying labour market topics. If data at more disaggregated levels were available, alternative types of regions (i.e., analytical regions) could be used and the aggregation method chosen (regionalization procedure) should be of major interest to researchers and policy makers.

When grouping data, lots of very well-known regionalization algorithms for spatial aggregation can be used.¹⁵ The purpose of these regionalization algorithms is basically to generate regions that are internally coherent but clearly different from each other. These algorithms minimize the objective function value in such a way that the intraregional heterogeneity is as low as possible. The methods assume certain prior knowledge about the relevant variable (or variables) for aggregation, the number of regions to be designed or the existence of contiguity constraints, so in this sense they are supervised.

¹⁵ For a review of the literature on regionalization methods, see Fischer (1980), Murtagh (1985), Gordon (1996; 1999) and Duque *et al.* (2006).

Source: Authors' calculations based on 2001 Spanish Census (INE, 2007).

Applying the original classification to the particular characteristics of the Spanish case,¹⁶ the classification would be as follows:

Metropolitan areas (MA): The same 500,000 threshold in other countries is used in the Spanish case to define metropolitan areas. However, given the special demographics of Spanish cities, metropolitan areas are subdivided into two classes. The first, MA1, includes metropolitan areas with more than two and a half million inhabitants. The second, MA2, refers to metropolitan areas with a population of between 500,000 and 2,500,000 inhabitants.

Urban areas (UA1 and UA2): The urban agglomerations with more than ten thousand inhabitants are grouped into two classes. The first, UA1, includes all areas with more than 100,000 inhabitants and less than 500,000; the second, UA2, all urban areas with populations between 10,000 and 100,000 inhabitants.

Rural areas (RA): all areas that are not urban, which may contain towns, but with less than ten thousand inhabitants in 2001.

The hour's drive criterion also holds in the Spanish case:

Central areas (CA): all areas within approximately one hour's drive of a metropolitan area (either MA1 or MA2).

Peripheral areas (PA): all areas situated more than one hour's drive from metropolitan areas (either MA1 or MA2).

Thus, taking into account the particular demographic structure and city size characteristics, in the Spanish case eight types of regions were created. Table 3 presents a summary of the eight types of regions based on the size and distance criteria into which the 8,106 Spanish municipalities are aggregated.

In line with this classification, in Map 1 we can see the resulting division of Spanish territory, an unfamiliar and novel landscape where these “types of regions” do not necessarily share borders (there is no contiguity constraint) or

¹⁶ A strict application of the original definition of “metropolitan area” (areas with more than 500,000 inhabitants) in the Spanish case generates two clear sub-groups: Madrid and Barcelona Metropolitan Areas (which both concentrate more than 4 million inhabitants), and the rest of the Spanish metropolitan areas (with populations less than 1.5 million in all cases). Similarly, two categories of *urban* regions are created (less than or more than 100,000 inhabitants). For more details, see Appendix I.

belong to the same politico-administrative region, i.e. a NUTS III region (province) or NUTS II region (Autonomous Community)¹⁷.

**Table 3. Territorial classification by size and position.
Application to the Spanish case.**

Metropolitan areas (MA) of more than 2,500,000 inhabitants (¹)	MA1	
Metropolitan areas of between 500,001 and 2,500,000 inhabitants (²)	MA2	
	Central Urban Areas (no more than a one hour drive from a MA)	Peripheral urban areas (more than a one hour drive from a MA)
Urban areas of between 100,001 and 500,000 inhabitants (³)	CUA1	PUA1
Urban areas of between 50,001 and 100,000 inhabitants	CUA2	PUA2
Rural areas, less than 50,000 inhabitants	CRA	PRA

Notes:

(¹) Metropolitan Areas of Madrid and Barcelona.

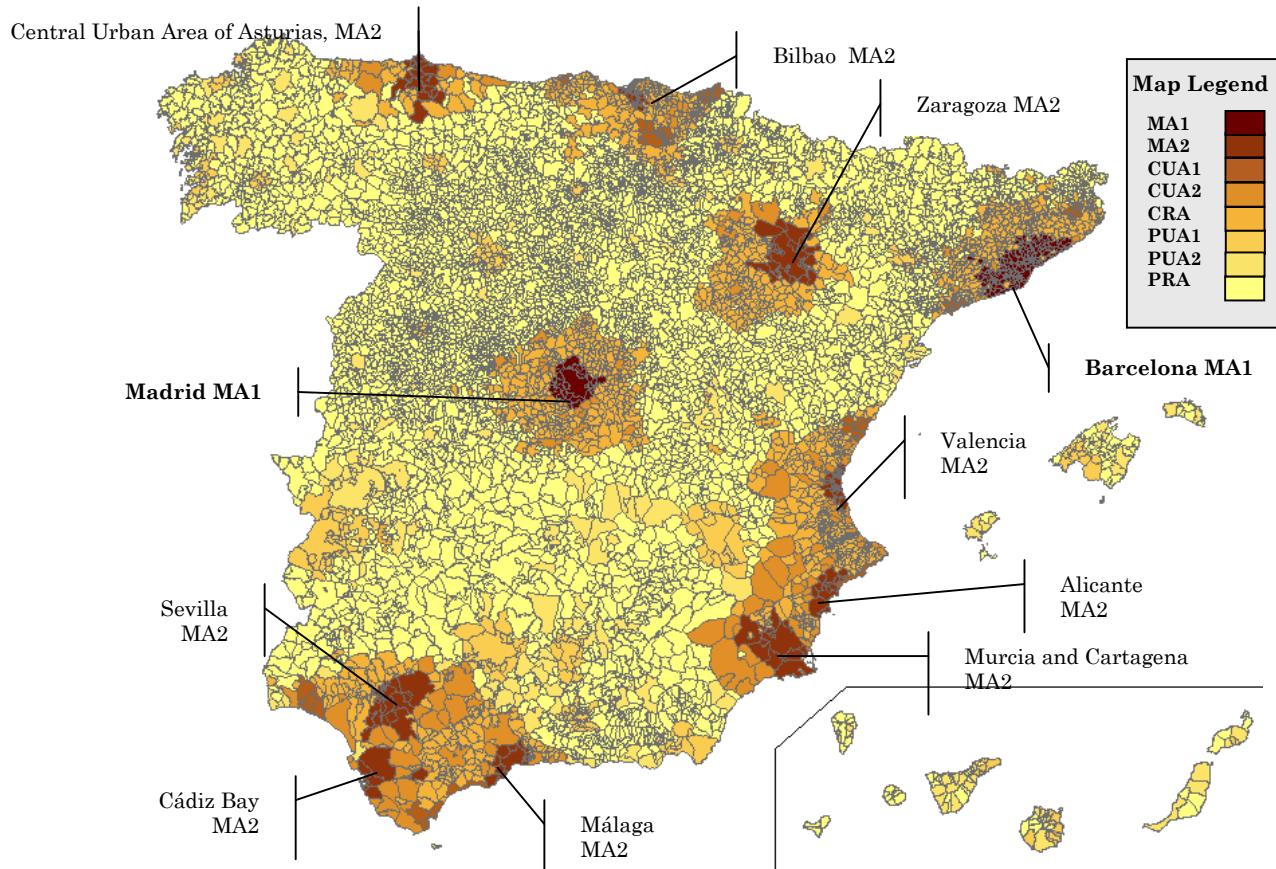

(²) Metropolitan Areas of Alicante, Bilbao, Cadiz Bay, the Central Urban Area of Asturias, Malaga, Murcia and Cartagena Conurbation, Seville, Valencia and Zaragoza.

(³) There are more than 200 municipalities that can be classified as “urban” and “central”, with the most important ones being Castellon, Girona, Huelva, Malaga, San Sebastian, Santander-Torrelavega, Tarragona, Vitoria and some of their surrounding municipalities.

Source: Polèse *et al.* (2007).

¹⁷ As Fischer (1980) points out, “The main distinguishing characteristic between regions and regional types is the spatial contiguity of the spatial basic units.”

Map 1: Spanish Territory into the Eight Analytical Types of Regions

Source: Own elaboration based on Polèse *et al.* (2007) and Viñuela *et al.* (2010).

Although this paper does not deal directly with the labour economics literature on local labour markets, i.e., the analytical areas were not constructed using any sort of commuting criteria, it can be easily proved that the travel-to-work commuting patterns of these functional regions generated under the size and proximity criteria also fit into the definition of a local labour market area. This is an additional positive feature of the analytical regions as it is agreed that the LLMAs are the ideal geographical areas for the implementation of any regional industrial policy or for reporting disaggregated labour figures (Ball, 1980).

Table 4 shows commuting patterns for the eight types of regions under analysis. The metropolitan areas and the regions that include the bigger municipalities (cities with more than 100,000 inhabitants and their surrounding areas or influence)¹⁸ would also strictly fulfil the 75% threshold for commuting patterns

¹⁸ As suggested by Papps *et al.* (2002), “The metropolitan area system is not designed to deal with rural areas” (p. 6).

set in the labour economics literature, i.e., they are self-contained local labour markets -or travel-to-work areas- from both the demand and the supply side.

Table 4: Commuting patterns between the Analytical Regions.

Analytical Regions	MA1	MA2	CUA1	CUA2	CRA	PUA1	PUA2	PRA
Percentage of people working in the residence region	91.2	89.5	84.3	69.6	59.3	87.7	77.7	65.8
Percentage of people living in the working region	88.1	84.6	75.4	69.2	68.6	76.2	79.5	83.9

Source: Authors' calculations based on 2001 Spanish Census (INE, 2007).

Besides the accomplishment of the commuting criteria, in theory an optimal region should fulfill at least one of two principles (Fischer, 1980): *internal homogeneity*, whereby individual regions should be as homogeneous in the attribute space as possible, and *external separation*, whereby different regions should be as far apart in the attribute space as possible. Pursuing both principles, on the next section we will evaluate the robustness of the functional regions suggested versus the administrative ones commonly used (NUTs at different levels) for the study of the Spanish labour markets.

3. Evaluation of the analytical classification.

3.1. Evaluation criteria.

Although no statistical algorithm or method has been used for the definition of the analytical regions, when evaluating them versus the traditional administrative division, same criteria proposed for clustering evaluation and selection of an optimal clustering scheme applies: (i) *Compactness*, i.e., the members of each region should be as close to each other as possible; and (ii) *Separation*, i.e., the regions themselves should be widely spaced¹⁹.

Applied to local labour markets, the first criteria (internal homogeneity) imply the existence of very well defined labour markets where the municipalities included

¹⁹ There are different approaches to measuring the distance between two regions: distance between the closest members of the regions (single linkage), between the most distant members (complete-linkage) or between the centers of the clusters (comparisons of centroids). See Berry and Linoff (1996).

share common characteristics, problems and diagnosis. This compactness is a desirable feature for any active labour policy designed to be implemented at local level. As for the second criteria (dissimilarity between regions), the existence of differences between regions in practical terms implies the spatial customization of policies, i.e., policymakers should be very aware of the economic characteristics of each region in order to try to identify its particular problems. In other words, the success of a policy in a certain region does not guarantee its immediate success in another.

3.2. Hypotheses.

To evaluate the relative performance of the analytical ones designed under economic criteria versus the traditional administrative regions (NUTS I, NUTS II and NUTS III regions), we will test the following hypothesis:

H1: given the existence of agglomeration economies and the importance of location, the analytical regions are better for describing the *employment* distribution patterns, either *total* or *by gender*, in the Spanish territory than any of the administrative divisions.

H2: the analytical regions capture the patterns of distribution of *employment by industry* better than the administrative regions commonly used.

H3: the spatial distribution of *employment by type of job performed and level of qualification* can be better explained on bases of the analytical regions than any of the administrative divisions commonly used.

3.3. Evaluation indexes: Theil inequality index and Davies-Bouldin Validity Index.

To test the three hypothesis we will use the well-known Theil inequality index (Theil 1967), commonly applied to the distribution of income and wealth. The index can be decomposed as the sum of the *between* and a *within* component²⁰. Its *within* component will be useful to quantify the intraregional homogeneity of the regions when dealing with the spatial distribution of

²⁰ For more details about the calculation of the Theil index, see Appendix II.

employment. Given the characteristics of Theil's index, if the internal homogeneity of the regions increases (a decrease of the within component), that necessarily implies that the heterogeneity between regions increases (a rise of the *between* component). Nowadays, in reality this is not necessarily the case; a given region may be very well defined internally but exhibit no particular differences from another (the reverse also applies).

In order to include both criteria simultaneously –*compactness* and *separation*–, we have to use techniques specifically designed for clustering validation. Thus, it seems necessary to test also the three hypotheses with the Davies-Bouldin Validity Index (Davies and Bouldin, 1979)²¹. Given the characteristics of our database and the administrative and analytical classifications of the regions (non-hierarchical crisp clusters with different numbers of regions), the Davies-Bouldin index is the most appropriate clustering validation technique as it exhibits no trends with respect to the number of regions²². This index estimates the average similarity between each region and the most similar one to it, so small values of the index are indicative of the presence of compact and also well-separated regions.

3.4. Evaluation results.

The first hypothesis under scrutiny is related to the use of the functional regions or the administrative ones for the study of the spatial distribution of employment and the distribution of employment by gender.

Table 2 shows the within component of the Theil's index and the Davis-Bouldin index (total and by gender) when the 8,106 Spanish municipalities are aggregated into administrative regions –NUTS I (7 regions), NUTS I (17 *Comunidades Autónomas*), NUTS III (50 *Provinces*)- and into the analytical regions suggested (8 regions).

²¹ For more details about the calculation of the Davies-Bouldin index, see Appendix III.

²² For a good review of the main clustering validation techniques, see Halkidi et al, 2001).

Table 2: Analytical versus administrative regions. Theil's index and Davis-Bouldin index (Employment, total and by gender).

		Analytical Regions			Administrative Regions

Source: Authors' calculations based on 2001 Spanish Census (INE. 2007)

Despite of the scale effect, i.e., everything else equal, intraregional inequality drops with the number of regions, the *within* component for the eight analytical regions is clearly lower than for any of the NUTS regions. In other words, the classification proposed shows a higher degree of internal homogeneity in the distribution of employment so that the local labor markets generated under the size and distance criteria are more integrated or coherent (even by gender) than any other political-administrative division of the territory.

The Davies-Bouldin index also shows better results (lower value of the index) for the analytical regions than for any other type of normative division. Surprisingly enough, when taking into account internal homogeneity and also heterogeneity between regions (the main advantage of the DB index), NUTS I regions show better results than the NUTS II or NUTS III regions. This proves that despite being made up of *Comunidades Autonomas* with a higher degree of internal heterogeneity, the NUTS I division "artificially created" for comparison purposes within the European Union at least manages to divide the Spanish territory into seven large areas which are clearly differentiated and pretty homogeneous: North-West, East, North-East, Madrid, Centre, South and Canary Islands. In any case, however, the results for the eight analytical regions are better.

As expected, we can talk about one labor market for men and another one for women. These are two different labor markets –also at regional level-, that

show a higher level of homogeneity – and heterogeneity between them - when studied separately.

The second hypothesis under scrutiny is related to the spatial patterns of distribution of employment by industry. The 2001 Spanish Census offers employment figures for sixteen (16) types of industries²³. Results for the Theil index (total and decomposed) and the Davis-Bouldin index according to the industrial classification used in the Census (Table 3) show a higher internal homogeneity within and also heterogeneity between the analytical regions for all industries except “Agriculture, hunting and forestry activities and fishing” and “Extractive Industries”. One simple explanation is that these particular activities are necessarily linked to the physical location of the natural resources at hand - land, forests, rivers or mines- and therefore the chances to *choose* the geographical location of employment or for employment to move *freely* are very limited. In other words, the distribution of these activities does not depend on agglomeration economies but on the location of the natural resources.

²³ “Agriculture, Hunting and Forestry Activities” and “Fishing” have been aggregated, therefore results only show 15 types of industries.

Source: Authors' calculations based on 2001 Spanish Census (INE. 2007)

For testing the third hypothesis, i.e., the analytical regions are a better option - more compact and differentiated-, when dealing with spatial analysis of labor markets by different levels of qualification, the classification available at the 2001 Census describes 9 groups aggregated by type of work and level of qualification. In this special classification, qualification is understood as the capacity to carry out the tasks which comprise any given job. Therefore, it includes two different facets: level of qualification and specialization within this

level qualification. In order to work with a more standard classification, we aggregate those 9 groups into “High-Qualified Occupations”, “Medium-Qualified Occupations” and “Low-Qualified Occupations”²⁴. The results of the Theil and Davis-Bouldin index by level of qualification are shown in the following table (Table 4)²⁵.

Table 4: Analytical versus administrative regions. Theil's index and Davis-Bouldin index (Employment by occupation).

	Analytical Regions		Administrative Regions		
	MA1 to PRA (5 Regions)	Within	NUTS III (PROV) (50 Regions)	NUTS II (CCAA) (17 Regions)	NUTS I (7 Regions)
Theil's Index					
High Qualified	29.78	15.25	22.96	24.36	24.90
Medium Qualified	23.30	11.34	17.22	18.58	19.13
Low Qualified	23.21	11.18	17.05	18.35	18.95
Davis-Bouldin					
High Qualified		19.55	149.06	503.67	64.94
Medium Qualified		28.18	681.13	167.34	99.87
Low Qualified		33.68	330.02	402.27	64.77

Source: Authors' calculations based on 2001 Spanish Census (INE, 2007).

For all levels of qualification, the within component is clearly lower than any other administrative division. The differences are slightly more pronounced for the high qualified jobs, where agglomeration economies might play a more effective role.

For the third hypothesis tested, namely the suitability of the analytical regions for the study of the spatial patterns of distribution of employment by level of qualification and occupation, the Davis-Bouldin index confirms those from the Theil index. The analytical regions are also a better option when dealing with local labor market issues by level of qualification or occupation.

²⁴ For details about the nine categories and their aggregation, see Appendix IV.

²⁵ See Appendix V for Theil's Index results for the nine categories.

4. Conclusions.

To date, analysis of the spatial dimension of Spanish labor market has been limited to administrative, rather than appropriately-defined functional, geographic units. Alternative divisions of the territory based on the existence of agglomeration economies and the importance of geography have been used in the literature to understand the location of economic activity (Polèse *et al.*, 2007) or explain the employability patterns (Viñuela *et al.*, 2010). However, their robustness against the administrative ones commonly used has –to date- not been evaluated. The objective of this paper is to prove those functional regions defined under such economic criterion provide better defined regions –more compactness and separation- than the administrative ones commonly used to carry out labour market studies at sub-national level.

Using micro data from the last Spanish Census available, the functional and administrative regions are evaluated using the Theil index and the Davis-Bouldin Validation index. Applied to employment (by gender, industry and level of qualification and occupation), both indexes show better results for the analytical regions than for any of the ordinary administrative ones (NUTS I, II or III regions). The analytical classification generates areas where the distribution of employment is more homogeneous within and more heterogeneous between the regions. Agglomeration economies and distance (to the metropolis) seem to be relevant for understanding the patterns of distribution of employment, either by gender, by industry or by level of qualification and occupation. In practice this means a clearer way for identifying local labour markets and explaining their differences and similarities.

In the light of these results, this paper suggests that, subject to the availability of data, this alternative classification could be considered when carrying out labor economics studies that include a *spatial* dimension. The use of this classification can offer a better understanding of the job opportunities, location of industries, concentration of unemployment, occupations and so many other labour related topics. Surpassing the administrative division of the territory, this classification manages to have explanatory power in spatial labour economics topics while including geoeconomic characteristics as relevant as location and agglomeration economies.

PUA1	5,587,002	259
PUA2	3,970,633	193
PRA	5,318,132	5,321
Total	40,709,455	8,106

APPENDIX II: Decomposition of the Theil's inequality index.

Applying the Theil inequality index (Theil 1967) to employment, the formula is computed as follows:

$$T = \sum_{m=1}^n \frac{PopEmp_{municip}}{PopEmp_{Esp}} \log \left(\frac{PopEmp_{municip} / PopEmp_{Esp}}{1/n} \right)$$

where n is the number of municipalities considered (8,106), $PopEmp_{municip}$ is the population employed in municipality m , and $PopEmp_{Esp}$ represents the Spanish working population.

The Theil index can be completely and perfectly decomposed into a *between-group* component (Tg) and a *within-group* component (Tw). Intraregional homogeneity can be therefore quantified by the within-group component. Thus:

$$T = Tg + Tw$$

with

$$Tg = \sum_{r=1}^R \frac{PopEmp_r}{PopEmp_{Esp}} \log \left(\frac{PopEmp_r / PopEmp_{Esp}}{n_r / n} \right)$$

$$Tw = \sum_{r=1}^R \frac{PopEmp_r}{PopEmp_{Esp}} \sum_{m=1}^n \frac{PopEmp_{municip}}{PopEmp_r} \log \left(\frac{PopEmp_{municip} / PopEmp_r}{1/n_r} \right)$$

where r indexes regions, with n_r representing the number of municipalities in region r and $PopEmp_r$ the population employed in the region r to which the municipality belongs.

As the within component quantifies the heterogeneity between the individuals of a region, small values indicate the existence of a high degree of internal homogeneity.

APPENDIX III: The Davies-Bouldin Validation Index.

This index (Davies and Bouldin, 1979) is a function of the ratio of the sum of within-region scatter to between-region separation, and it is defined as:

$$DB_m = \frac{1}{m} \sum_{i=1}^m R_i$$

where $R_i = \max_{j=1, \dots, m, j \neq i} R_{ij}$, $i = 1, \dots, m$ and m is the number of regions in which the Spanish territory is divided for each classification.

Then, the similarity index R_{ij} between region i (R_i) and region j (R_j) is defined as:

$$R_{ij} = \frac{S_i + S_j}{d_{ij}}$$

where S_i is a measure of dispersion of R_i and $d(C_i, C_j) \equiv d_{ij}$ the dissimilarity between two regions. The index R_{ij} satisfies the following:

1. $R_{ij} \geq 0$
2. $R_{ij} = R_{ji}$
3. if $S_i = 0$ and $S_j = 0$ then $R_{ij} = 0$
4. if $S_j > S_i$ and $d_{ij} = d_{ik}$ then $R_{ij} > R_{ik}$
5. if $S_j = S_i$ and $d_{ij} < d_{ik}$ then $R_{ij} < R_{ik}$.

The dissimilarity between region R_i and region R_j , in a l -dimensional space is defined as:

$$d_{ij} = \left\| \overline{\text{EmpPop}_i} - \overline{\text{EmpPop}_j} \right\| = \sqrt{\sum_{k=1}^l \left| \overline{\text{EmpPop}_{ik}} - \overline{\text{EmpPop}_{jk}} \right|^2}$$

and the dispersion of a region R_i is defined as:

$$S_i = \sqrt{\frac{1}{n_i} \sum_{x \in R_i} \left\| \text{EmpPop} - \overline{\text{EmpPop}_i} \right\|^2}$$

As DB_m is the average similarity between each region and its most similar one, small values of DB are indicative of the presence of compact and well-separated regions. The DB_m index exhibits no trends with respect to the number of regions.

APPENDIX IV: Type of job and level of qualification according to the 2001 Census classification and broad aggregation.

CN01 CLASSIFICATION (2001 Spanish Census)	AGGREGATION
1 -Business and public administration management/managers	Highly-skilled personnel: directors, highly-qualified professionals and skilled technical staff
2 - Technical staff and scientific and intellectual professionals	
3 - Technical and professional support staff	
4 - Administrative staff	
6 - Skilled workers in agriculture and fisheries	Medium-skilled personnel: technical staff and administrative support staff
7 - Artisans and qualified workers in manufacturing, construction and mining excluding machine operators and installation workers	
5 - Hostelry, security and retail sales workers	
8 - Machine operators, installation workers and fitters.	Low-skilled personnel: tertiary workers and industrial, artisanal and agricultural operators/laborers
9- Unskilled workers	

APPENDIX V: Decomposition of the Theil inequality index by level of qualification and occupation (9 categories).

		Administrative Regions			Analytical Regions
